Summary

2,5-Diamino-3,6-dinitropyrazine (ANPZ-i) has been prepared via the electrophilic nitration of 2,5-diethoxypyrazine using nitronium tetrafluoroborate in sulpholane and subsequent amination under autoclave conditions. Molecular modelling studies have been carried out which indicate that ANPZ-i should have a similar performance to RDX but with an expected higher insensitivity. ANPZ-i (1) is therefore a novel candidate high energy insensitive explosive.

1. Introduction

Existing explosives such as TNT or RDX are very powerful, but suffer from a high sensitivity (thermal and mechanical). Several approaches can be adopted in order to render the system insensitive, e.g. by the use of inert and energetic binders. An alternative approach is the incorporation of amino groups into the explosive, for example TATB (1,3,5-triamino-2,4,6-trinitrobenzene) is very insensitive, however lacks sufficient power output. It has been postulated that the insensitivity in TATB arises from intramolecular hydrogen bonding between adjacent amino and nitro groups.

The aim of this research was therefore to prepare high energy compounds, with a similar performance to RDX, but with also a high insensitivity. Nitrogen heterocyclic compounds are considered to be ideal for this application since they inherently contain nitrogen in the form of the ring heteroatoms. Additionally, functionalisation with nitro and amino groups should impart insensitivity to the molecule. This work was carried out within DERA Chemical Technology Department, where highly integrated research is carried out drawing from disciplines such as molecular modelling, physical and chemical characterisation, hazard assessment, formulation, scale-up and of course bench synthetic chemistry.

2. Results and Discussion

The preparation of ANPZ (2,6-diamino-3,5-dinitropyrazine) and PZO (2,6-diamino-3,5-dinitropyrazine-N-oxide) has been reported by researchers at LLNL, Livermore, California (USA)(1). The synthesis of these explosive molecules was repeated and found to be relatively straightforward. Consequently, it was decided that the isomer of ANPZ: 2,5-diamino-3,6-dinitropyrazine (ANPZ-i, 1) and its dioxide derivative: 2,5-diamino-3,6-dinitropyrazine-1,4-dioxide (PZDO, 2) would be attractive target explosive molecules (Scheme 1).

Initially, the ethylation of piperazine-2,5-dione (3) was found to be problematic(2). It is thought that commercially available triethylxonium tetrafluoroborate or Meerwein’s salt is contaminated with fluoroboric acid. The fluoroboric acid protonates 3 forming an unreactive salt.

Triethylxonium tetrafluoroborate was therefore generated in situ, by the reaction between epichlorohydrin and boron trifluoride diethyl etherate, and then used in the alkylation of piperazine-2,5-dione. It is essential that the Meerwein’s salt is prepared in dry conditions and therefore all the reagents were freshly distilled and the reaction was kept under nitrogen at all times. The Meerwein’s salt is formed in quantitative yield and is kept in the reaction vessel.
where it is used to alkylate 3 in dichloromethane solvent again in very high yield. Aromatization of 2,5-diethoxy-3,6-dihydropyrazine (5) also proceeds very smoothly and 2,5-diethoxypyrazine (6) is produced in high yield (3). Both the 2,5-dimethoxy-3,6-dihydropyrazine and 2,5-dimethoxypyrazine were also prepared.

The oxidative nitration of 2,5-diethoxy-3,6-dihydropyrazine (4) was attempted a number of times using N₂O₅ as detailed in the literature(4). For each reaction a decomposition product was obtained and it is the author’s opinion that this reaction is not repeatable.

The electrophilic nitration of 2,5-diethoxypyrazine (5) was attempted with a wide range of conditions (Table 1). Mixed acid nitration of 5 resulted in an extremely violent reaction where decomposition of the starting material was instantaneous above a specific temperature (c. -10°C). Therefore, it was thought that a milder nitrating agent would be more effective for the nitration of this highly activated aromatic species.

The use of nitronium tetrafluoroborate in sulpholane was found to be effective in dinitrating 5, typically with a yield of 30–40%. A range of conditions were used in order to optimize this reaction (Table 2), however, the optimum yield appears to be c. 35–40%. It is thought that the relatively low reaction yield with the tetrafluoroborate salt may be due to decomposition of the salt.

2,5-Diethoxyppyrazine was also successfully nitrated using nitronium hexafluoroantimonate (V) in dry sulpholane with a reaction yield of 35%, however a large excess of the nitrating agent was required in order to achieve this reaction yield.

The amination of 2,5-diethoxy-3,6-dinitropyrazine (6) was attempted using aqueous ammonia in acetonitrile at atmospheric pressure, however, unreacted starting material was recovered. Therefore, amination of the substrate was attempted with an ammonia saturated solution of methanol under autoclave conditions; 2,5-diamino-3,6-dinitropyrazine (1) was obtained in 95% yield.

Both HPLC and IR analysis indicated the presence of a pure compound and the 60 MHz ¹H NMR spectrum showed only the presence of amino protons, which collapsed and formed a doublet on D₂O addition, with no ethoxy proton signals present. ¹³C NMR analysis has also been carried out. Detonics studies using MOLPAK and Cheetah calculations have given the following predicted data (Table 3) for ANPZ-i (1) and PZDO (2).

### Scheme 1. Proposed preparation of 2,5-diamino-3,6-dinitropyrazine-1,4-dioxide (PZDO) via ANPZ-i
Therefore, ANPZ-i has a predicted performance roughly equal to that of RDX but with an envisaged higher insensitivity.

A number of attempted oxidations of 2,5-diamino-3,6-dinitropyrazine (I) were carried out using 30\% hydrogen peroxide and trifluoroacetic acid \textit{(in situ} generation of trifluoroacetic acid). Typically upon work-up of the reaction mixture no product could be obtained since the starting material/product could not be extracted from the aqueous acidic layer. Also, only negative ferric chloride tests were observed\(^{6}\). Further oxidation systems were used in the attempted oxidation of I including MCPBA (\textit{meta}-chloroperbenzoic acid), DMD (dimethyldioxirane)\(^{5}\) and HF/MCPBA all without success.

By comparison of the structures of ANPZ (2,6-diamino-3,5-dinitropyrazine) and ANPZ-i (2,5-diamino-3,6-dinitropyrazine), the former is readily oxidized to the mono-N-oxide since the oxide is flanked by two amino groups and hence stabilized by intramolecular hydrogen bonding. Conversely, with the structure of ANPZ-i, both mono- and di-oxidation would lead to an N-oxide group being flanked by one amino group and one nitro group. It is suspected that this change in electronic environment of the oxide group is responsible for the difficulty in oxidising ANPZ-i when compared to ANPZ.

To summarize 2,5-diamino-3,6-dinitropyrazine (ANPZ-i), which is a novel explosive compound, has been prepared and fully characterized. ANPZ-i was prepared via the electrophilic nitration of 2,5-dioethyloxyryazine using nitronium tetrafluoroborate in sulpholane and subsequent diamination under autoclave conditions. The N-oxidation of ANPZ-i was not achieved despite the use of a wide selection of oxidation systems.

Molecular modelling of ANPZ-i has shown it to have approximately equal performance to RDX but with an envisaged higher insensitivity. Additionally, its calculated performance is significantly higher than that of TATB. It is hoped that in the future larger amounts of ANPZ-i will be produced for hazard testing.

### 3. Experimental

Commercial chemicals were supplied by the Aldrich Chemical Co. at the highest purities available (generally \( > 98\% \)) and were used as received. \(^{1}\)H and \(^{13}\)C NMR spectra were recorded on either a Bruker MSL-300 FT-NMR spectrometer (300 MHz) or a Varian EM 360A spectrometer (60 MHz) at ambient temperature using TMS as the internal reference for. Mass spectral (MS) analysis was carried out using a VG 7070EQ mass spectrometer. Spectra were acquired in \(\text{EI} \) mode between masses 10 and 400 at 1 \(\text{s}^{-1} \) while the probe was heated at 5\(\text{°C} \text{s}^{-1} \) from ambient temperature to 650\(\text{°C} \). IR spectral measurements were carried out using a Nicolet 710 FT-IR spectrometer equipped with MCT(A) detector. Liquids were characterized as films between KBr plates and solids as KBr discs. HPLC analyses were performed on an ATJ Unicam Diamond 600 system using 22 cm \(\times\) 5 mm i.d. columns with Lichrosorb RP18 (7 \(\mu\)) packings (Merck); the eluent was acetonitrile-water 50:50 \(\text{v/v} \) at flow rate 1.0 \(\text{ml min}^{-1} \), and monitoring wavelength 254 nm.

#### 3.1 Triethylonium Tetrafluoroborate (Meerwein’s salt)

To a stirring solution of boron trifluoride diethyl etherate (freshly distilled over \(\text{CaH}_2\)) (140 ml, 157 g, 1.39 mol) in dry diethyl ether (freshly distilled over sodium) (300 ml) was added drop by drop epichlorohydrin (freshly distilled over \(\text{MgSO}_4\)) (66 ml, 78.1 g, 1.03 mol). The addition was carried out at such a rate that the reaction mixture gently refluxed and would typically take 15 minutes. Throughout the addition of reagents the reaction must be kept under a constant stream of nitrogen so as to ensure very dry conditions. The reaction mixture was then refluxed for 1.5 hours and left to stand at room temperature overnight. The condenser was replaced with a filtration stick (inside a rubber septum) and whilst still under a positive pressure the liquid was removed from the reaction vessel by vacuum suction. The white solid that remained in the reaction vessel was washed with cold, dry diethyl ether (3 \(\times\) 250 ml) with the solvent each time removed via the filtration stick. Approximately 145 g of pure white solid, triethylonium tetrafluoroborate, was left in the reaction vessel. M.Pt. = 92\(\text{°C} \). (Lit. 91–92\(\text{°C} \), decomposition\(^{7}\)).

#### 3.2 2,5-Dioethoxy-3,6-Dihydropyrazine (4, R = Et)

To the Meerwein’s salt (~145 g) from the previous experiment was added freshly distilled dichloromethane
(350 ml) and then piperazine-2,5-dione (dried overnight) (32.9 g, 0.29 mol). The resulting mixture was then stirred at room temperature and under nitrogen for 5 days; after the first day a large amount of sticky white solid is generated in the reaction vessel and the liquid changes from colourless to light brown. After the 5 days the reaction mixture was quenched with aqueous sodium hydroxide solution (2.5 M) and the organic layer separated. The aqueous layer was washed with dichloromethane (2 × 125 ml) and the organic layers combined, dried over MgSO4, filtered and concentrated in vacuo to yield a light brown fluffy solid (28.0 g, 0.160 mol, 71% yield).

M.Pt.: 83–85°C (lit. 84°C)\(^3\)

\[\delta^1\text{H} (60 \text{ MHz, CDCl}_3): 1.30 (6\text{H, t, }2 \times \text{Me}), 4.10 (4\text{H, s, }2 \times \text{NCH}_2), 4.15 (4\text{H, q, }2 \times \text{CH}_2\text{O}).\]

\[\delta^{13}\text{C} (75 \text{ MHz, CDCl}_3): 14.30 (\text{CH}_3), 46.65 (\text{C-3 and C-6}), 128.75 (\text{OCH}_2), 162.70 (\text{C-2 and C-5}).\]

\[\nu_{\text{max}}(\text{cm}^{-1}): 1690 (\text{C} = \text{N}), 2350 (\text{C-H}).\]

3.3 2,5-Diethoxy-3,6-Dihydropyrazine (5, \(R = \text{Et}\))

A stirring suspension of 2,5-diethoxy-3,6-dihydropyrazine (2.00 g, 12.0 mmol), NCS (1.80 g, 13.0 mmol) and AIBN (0.03 g, catalytic amount) in carbon tetrachloride (40 ml) was slowly heated under an atmosphere of nitrogen to 80°C. At around 70°C the suspension changed to a homogeneous mixture, indicating that the reaction had commenced. The stirring mixture was heated under reflux overnight (15 h), whereupon it was allowed to cool to 0°C. The succinimide was filtered off and washed with carbon tetrachloride (25 ml). The organic layers were then combined and the solvent removed in vacuo to yield a pink liquid (1.83 g, 10.9 mmol, 90.5% yield).

\[\delta^1\text{H} (60 \text{ MHz, CDCl}_3): 1.35 (6\text{H, t, }2 \times \text{CH}_3), 4.30 (4\text{H, q, }2 \times \text{OCH}_2), 7.75 (2\text{H, s, Ar-H}).\]

\[\delta^{13}\text{C} (75 \text{ MHz, CDCl}_3): 15.00 (\text{CH}_3), 62.80 (\text{OCH}_2), 128.75 (\text{C-3 and C-6}), 156.28 (\text{C-2 and C-5}).\]

\[\nu_{\text{max}}(\text{cm}^{-1}): 1685 (\text{NCH}_2), 2986 (\text{C-H}), 1554 (\text{NO}_2 \text{ asymm.}), 1335 (\text{NO}_2 \text{ symm.}).\]

\(m/z: 258 (\text{M}^+), 259 (\text{M}^+ + 1).\)

3.5 2,5-Diamino-3,6-Dinitropyrazine (I)

Ammonia gas was bubbled through dry MeOH (35 ml) in an autoclave vessel for 5 minutes then 2,5-diethoxy-3,6-dinitropyrazine (350 mg, 1.40 mmol) was added. The reaction mixture was heated in the sealed autoclave system for 4 hours (150°C, 1.72 MPa). The autoclave was then allowed to cool down to room temperature whereupon the reaction mixture was added to acetonitrile, but a precipitate did not form as expected. Therefore, the ammonia saturated acetonitrile/methanol solvent was allowed to evaporate at room temperature to leave a dark yellow solid, 2,5-diamino-3,6-dinitropyrazine (270 mg, 1.40 mmol, ~98% yield).

M.Pt. = 288°C (decomposition point).

\[\delta^1\text{H} (60 \text{ MHz, CDCl}_3): 2.00 (\text{bs, }4\text{H, }2 \times \text{NH}_2).\]

\[\delta^{13}\text{C} (75 \text{ MHz, CDCl}_3): 149.49 (\text{C-NO}_2), 150.30 (\text{C-NH}_2).\]

\[\nu_{\text{max}}(\text{cm}^{-1}): 3387; 3316 (\text{NH}_2), 1632 (\text{NO}_2 \text{ asymm.}), 1248 (\text{NO}_2 \text{ symm.}).\]

\(m/z: 200 (\text{M}^+).\)

CHN Analysis, calculated: C, 24.08; H, 2.02; N, 42.00; O, 31.99. Found: C, 23.79; H, 2.99; N, 42.00; O, 31.22.

3.6 Attempted Oxidation of 2,5-Diamino-3,6-dinitropyrazine (I)

To a stirring suspension of 2,5-diamino-3,6-dinitropyrazine (100 mg, 0.500 mmol) in trifluoroacetic acid, TFA (15 ml) at a temperature of between 0°C and 5°C, with cooling by an acetone/dry ice bath, was added gradually 30% aqueous hydrogen peroxide solution (3 ml). The reaction mixture was then allowed to warm to room temperature and stirred for 3 days. After this period further 30% aq. H2O2 (2 ml) solution was added and stirring continued for 24 hours. The reaction mixture was then allowed to water and the acid neutralized with solid NaHCO3; any excess NaHCO3 was filtered off. The aqueous layer was then left to evaporate at atmospheric pressure and the solid that remained washed with acetone. The mixture was then filtered of any insoluble inorganic material and the acetone layer concentrated in vacuo to yield a brown solid. Mass spectral analysis of this solid showed it to be a decomposition product. Additionally, a negative ferric chloride test was observed\(^6\).

4. References

(6) N-oxides have been shown to give a characteristic orange/red colouration when added to aqueous ferric chloride solutions.
